LIST OF SYMBOLS

Symbol

C_p	The mean pressure coefficient, $\bar{p}/\frac{\rho}{2} U_\infty^2$
C_{p_d}	Mean pressure-difference coefficient for chevron columns, $p_F - p_B / \frac{\rho}{2} U_\infty^2$
$C_{p_d \max}$	Peak pressure-difference coefficient for chevron columns, $1/2 [p_F - p_B]_{\max} - (p_F - p_B)_{\min} / \frac{\rho}{2} U_\infty^2$
$C'_{p_{\max}}$	Peak pressure coefficient, $\frac{1}{2} (p'_{\max} - p'_{\min}) \frac{\rho}{2} U_\infty^2$
$C'_{p_{rms}}$	RMS pressure coefficient, $p'_{rms} / \frac{\rho}{2} U_\infty^2$
\bar{p}	The mean pressure, $\overline{p_i - p_\infty}$
p_i	Instantaneous pressure at surface piezometer
\bar{p}_B	Mean pressure acting on B tap
\bar{p}_F	Mean pressure acting on F tap
p'_{\max}	Local maximum pressure, $(p_i - p_\infty)_{\max}$
p'_{\min}	Local minimum pressure, $(p_i - p_\infty)_{\min}$
p'_{rms}	RMS value of the local fluctuating pressure, $[(\overline{(p_i - p_\infty)^2})]^{\frac{1}{2}}$
p_∞	Mean undisturbed pressure
U_∞	Reference wind speed at free-stream
ρ	Mass density of air
α	Azimuth angle of approach wind
$(\bar{})$	Time average

I. INTRODUCTION

A modeling test on the Standard Oil Company (Indiana) Building was studied at the Fluid Dynamics and Diffusion Laboratory of Colorado State University. The main purpose of this study was to determine characteristic features of wind pressures on exterior surfaces of the building. The re-entrant corners and the chevron column paces produce separated flows which can introduce large pressure fluctuations. Information on the magnitude of these pressure fluctuations, which can be obtained only from a wind-tunnel study, is important for the design of cladding panels to be used on the building surface.

The proposed building is approximately 1,100 ft high with a symmetric cross section approximately 200 ft by 200 ft. A 1:98 scale model was constructed for the top 300 ft of the building. This model building was subjected to an uniform flow near the entrance of the wind tunnel in an effort to isolate the pressure fluctuations produced by separation and reattachment of the flow. Mean pressures, peak pressures, and root-mean-square values of the fluctuating pressure were measured directly by high-response pressure transducers. Smoke was introduced into the flow to make the overall flow patterns visible. A motion picture* was made to provide a permanent record of the flow patterns for several wind directions. Results in this report are given in non-dimensional coefficients. The pressures for a particular design wind speed can be obtained by multiplying the reference design dynamic pressure by the appropriate coefficients.

II. EXPERIMENTAL APPARATUS

The main objective of this study was to measure the mean and fluctuating pressures on the exterior surface of a rigid model building. Since surface geometry of the building may introduce local flow characteristics, which produce major fluctuations of pressure, the model was tested in an uniform air stream in an effort to define these peculiar effects. Direct measurements of mean pressures, instantaneous peak pressures, and root-mean-square (RMS) values of the exterior surface pressures were made.

Descriptions of the model, the wind tunnels, and the instrumentation are given in the following sections.

2.1 Model Building

In order to obtain an accurate measurement of local pressure by means of piezometer taps, the model was constructed to as large a scale as possible without introducing serious blockage of the wind tunnel. A 1:98 scale replica of the upper 300 ft of the building was selected. The model was built from 3/8 in. thick "Lucite" sheets and the chevron column paces were modeled by cementing triangular plastic strips to the plane surface. Dimensions of the model building are shown in Figure 2-1. A photograph of the model building is shown in Figure 2-2.

Piezometer taps (1/16 in. dia.) were drilled normal to the exterior wall on the chevron columns, the re-entrant corners, and on the roof. Because of building symmetry, pressure taps were drilled on only one complete face and one re-entrant corner. These taps were placed in a band at a level approximately 150 ft below the top. After the critical azimuth angle was obtained from an initial test, more taps were drilled

on one side of another re-entrant corner and two adjacent chevron columns for a detailed study. Figure 2-3 shows the location and designation of each tap.

The model building was fastened on a turntable which can indicate the angle of rotation with an accuracy of ± 0.1 degree. Figure 2-4 is a sketch of the model and the turntable. The rotation angle of the model building can be read either from the voltage output of a potentiometer geared to the base or from the scale engraved on the turntable.

2.2 Wind Tunnels

The experimental investigation was conducted in two wind tunnels of the Fluid Dynamics and Diffusion Laboratory at Colorado State University. These are the meteorological wind tunnel (MWT) and the environmental wind tunnel (EWT). The MWT is a recirculating type with a normal cross section of 6 x 6 ft. The mean velocity in the test section can be adjusted continuously from 0 to 120 fps (Fig. 2-5). This facility is described by Plate and Cermak (1963). The EWT is an open-circuit type with a normal cross section, 8 ft high and 12 ft wide. A 150 hp AC motor is used to drive the blower. The mean velocity can be adjusted from 0 to 23 fps by varying the fan pitch. Figure 2-6 shows a plane view of the EWT.

When the model building was placed in the MWT, the maximum and minimum blockages were 22% and 17.3%, respectively. On the other hand, the maximum and minimum blockages in the EWT were 8.3% and 6.5%, respectively. It was intended to make all measurements in the EWT because of the small blockage. However, since the acoustical noise from the fan in the EWT produced pressure fluctuations, the level inside the EWT was comparable in magnitude to those produced by the local flow

instabilities, measurements on instantaneous peak, mean, and RMS of local pressures were conducted in the MWT. The flow visualization was conducted in the EWT.

2.3 Instrumentation

Six "Statham" differential pressure transducers (Model PM283) were used to measure the mean pressure and its fluctuating component. The transducers were mounted inside the model building and vinyl tubing (3 in. long, 1/8 in. I.D.) was used to connect each transducer to a pressure tap. Pressure transducers were calibrated against an electronic pressure monometer (Transonic type 120). Figure 2-7 shows the calibration curves of all six transducers.

A 1/8 in. standard pitot static tube, located 3 ft upstream and 2 ft above the model building, was used to measure the free-stream velocity. The static pressure tap of the pitot tube was also connected to the "Reference" port of the "Statham" transducers. With this arrangement, the pressure measured by the transducer was the pressure difference between the local surface pressure and the static pressure in the free-stream.

A multi-channel Visicorder (Model 1612) was used to record the mean and the fluctuating component of the local pressure. A 14-channel tape recorder (Ampex model) was employed to record the fluctuating pressure for future analysis. The root-mean-square (RMS) value of the fluctuating pressure was measured through a Disa True-RMS meter (Model 55 D35) together with a Mosely x-y plotter (Model 135). A Tektronix storage oscilloscope (Type 562) and a Hewlett-Packard Model 3440A digital voltmeter were used to calibrate the transducers and to check the output

signal during the experiment. Figure 2-8 is a block diagram of the measuring system. A general view of the equipment is shown in Fig. 2-9.

III. RESULTS

The output of all six pressure transducers were recorded simultaneously on the visicorder. The mean pressure, \bar{p} , and the instantaneous peak pressure, p'_{\max} , were determined from the recording chart. Figure 3-1 is a typical trace of the local pressure for position C_5 , C_6 , F_1 , F_2 , F_3 , and F_4 . The arrows at the left side of Fig. 3-1 indicate the zero recording level, i.e., at zero velocity. The RMS value of the local fluctuating pressure was measured by the RMS meter.

A typical trace of the RMS pressure vs azimuth angle is shown in Fig. 3-2.

3.1 The Mean Pressure Coefficient

The mean pressure coefficient, C_p , is defined as follows:

$$C_p = \frac{\bar{p}}{\frac{1}{2} \rho U_\infty^2} \quad (1)$$

where ρ is the air mass density, U_∞ is the reference wind speed at freestream and \bar{p} represents the local mean pressure measured with respect to the free-stream static pressure. Table 1 is the measure C_p for all taps at different azimuth angles. Table 2 shows the coefficient of mean pressure difference acting on the chevron columns. This was obtained by connecting the "High" port of the transducer to a F tap and the "Low" port to the corresponding B tap. The pressure difference coefficient is defined as:

$$C_{p_d} = \frac{p_F - p_B}{\frac{1}{2} \rho U_\infty^2} \quad (2)$$

where p_F represents the pressure acting on the F tap and p_B is the pressure acting on the B tap. Table 3 shows the local mean pressure, \bar{p} at different azimuth angles. Table 4 indicates the mean pressure difference acting on the chevron columns. These pressures have been computed for the design speed of 120 m.p.h.

3.2 The Peak Pressure Coefficient

The local peak pressure is defined as one half of the local maximum to minimum pressure fluctuation. Consider p'_{\max} as the local maximum pressure and p'_{\min} as the local minimum pressure, the peak pressure coefficient $C'_{p_{\max}}$ is defined as

$$C'_{p_{\max}} = \frac{\frac{1}{2} (p'_{\max} - p'_{\min})}{\frac{1}{2} \rho U_{\infty}^2} \quad (3)$$

Table 5 shows the local peak pressure coefficients.

The peak pressure between the F tap and B tap of each chevron column $C'_{p_{d\ max}}$ was also measured. Table 6 shows the peak pressure coefficient between two taps on each chevron column. Table 7 gives the local peak pressures and Table 8 the peak pressure on each chevron column for the design wind speed of 120 m.p.h.

An estimated maximum pressure profile with the pressure taps in the center of upwind face for a wind speed of 120 miles per hour is shown in Figure 3-1-A.

3.3 RMS Pressure Coefficient

The fluctuating pressure can be represented in a statistical sense by using a RMS meter to measure the root-mean-square value of the local

fluctuating pressure. Consider p'_{rms} as the RMS value of the local fluctuating pressure, the RMS pressure coefficient is then defined as

$$C'_{p_{rms}} = \frac{p'_{rms}}{\frac{1}{2} \rho U_\infty^2} . \quad (4)$$

Figure 3-3 is a plot of the local $C'_{p_{rms}}$ vs the azimuth angle α . The numerical values of $C'_{p_{rms}}$ are shown in Table 9.

The flow pattern at $\alpha = 0^\circ$ is shown in Fig. 3-4. Flow separates from one edge of the re-entrant corner and reattaches at the opposite edge of the re-entrant corner. From Fig. 3-3 or from Table 5 the RMS pressure coefficient, $C_{p_{rms}}$, of tap C_6 , which is located at the reattachment point, is found to have a higher $C_{p_{rms}}$ value than any other tap. Visualization of the flow also showed that as α was increased from zero the flow first separated from the first chevron column and reattached on the side surface of the building. Figure 3-5 is a picture of the flow pattern at an azimuth angle $\alpha = 25^\circ$. The flow reattached in the neighborhood of F_5 giving a maximum of $C_{p_{rms}}$ at this point (see Fig. 3-3). The RMS pressure coefficients of the taps downstream from F_5 have maxima near $\alpha = 25^\circ$. These maxima are a good indication that flow reattachment is taking place. Figure 3-6 shows the pattern of flow at an azimuth angle $\alpha = -15^\circ$. The flow is seen to be reattaching at C_6 which also corresponds to an instantaneous peak in Fig. 3-3.

3.4 Pressure on the Roof

The mean and fluctuating pressures on the roof of the building were measured along the center line. Definition of the mean and peak pressure coefficients are the same as in Eqs. (1) and (3) respectively. Table 10 gives values of C_p and $C_{p_{max}}$ at different locations on the roof.

Since the flow separated from the up-stream edge of the roof and did not reattach on the roof, smoke released from the down-stream portion of the roof was initially carried up-stream (see Fig. 3-6).

IV. CONCLUSIONS

Results of this study are summarized in the following statements:

(1) The maximum negative mean pressure coefficient measured in this study was 2.546 which occurred on tap D₂, at an azimuth angle of +14°. The maximum negative mean pressure coefficient measured on roof was 2.081 on tap T₇.

(2) The maximum peak pressure coefficient measured in this study was 1.630 which occurred on tap C₆ at an azimuth angle of +5°.

(3) The RMS pressure coefficient can be used to locate the reattachment point at a given azimuth angle. Or at a given location, a maximum in the value of $C_{p_{rms}}$ indicates that the flow has reattached at that location.

(4) This study was carried out in a uniform flow with a model of only the upper 300 ft of the building in an effort to isolate the separation-induced pressure fluctuations. In order to have a better understanding of the total aerodynamical effect on the building, a wind tunnel study with a smaller scale model of the entire building placed in a simulated atmospheric boundary layer should be undertaken.

Components of Max. Instantaneous Pressure Used to Estimate the Profile
in Figure 3-1-A.

(from Atlantic Richfield Buildings
model study)

(From U.S. Steel Building model
study)

$$\text{Total pressure} = (C_p + C_{p\max}) \frac{\rho U^2}{2}$$

For $\rho = 0.00207 \text{ slugs/ft}^3$ and

$$U_\infty = 176 \text{ ft/sec. (equivalent to 120 mph)},$$

the total pressure shown in Fig. 3-1-A becomes

$$\text{Total pressure} = (C_p + C_{p\max}) 32.09$$

TABLE 10. MEAN PRESSURE COEFFICIENTS FOR POSITIONS -- T_3 , T_4 , T_5 , T_9 ,
 T_{10} , T_6 , T_7 , T_8 , T_{11} , T_{12} . MEASURED WITH RESPECT TO FREE
 STREAM STATIC PRESSURE.

Dynamic Head = 0.86 mm of HG.

Date of Experiment =

Angles Measured in Degrees = +90 and -90.

Position of Tap

Azimuth					
angle	T_3	T_4	T_5	T_9	T_{10}
+90	1.273	-1.276	-1.410	-1.236	-1.312
-90	-0.999	-1.133	-0.900	-1.487	-1.312

Dynamic Head = 0.83 mm of HG.

Date of Experiment =

Angles Measured in Degrees = +90 and -90

Azimuth

angle	T_6	T_7	T_8	T_{11}	T_{12}
+90	-1.661	-1.803	-1.729	-1.791	-1.903
-90	-1.962	-2.081	-1.903	-1.788	-1.815
